└ 2.13: Mean Value Theorem

└ Rolle's Theorem

Draw several functions passing through these two points. Start with continuous, differentiable, and point out there is always a flat spot. Ask students: *must* there always be a flat spot? Give examples with corners, discontinuities.

Rolle's Theorem – Theorem 2.13.1

Let a and b be real numbers, with $a < b$. And let f be a function with the properties:

- $f(x)$ is continuous for every x with $a \leq x \leq b$;
- $f(x)$ is differentiable when $a < x < b$;
- and $f(a) = f(b)$.

Then there exists a number c with $a < c < b$ such that

$$f'(c) = 0.$$

Rolle's Theorem – Theorem 2.13.1

Let $f(x)$ be **continuous** on the interval $[a, b]$, **differentiable** on (a, b) , and let $f(a) = f(b)$. Then there is a number c strictly between a and b such that $f'(c) = 0$.

Example: Let $f(x) = x^3 - 2x^2 + 1$, and observe $f(2) = f(0) = 1$. Since $f(x)$ is a polynomial, it is continuous and differentiable everywhere.

2.13: Mean Value Theorem

Rolle's Theorem – Theorem 2.13.1

Let $f(x)$ be continuous on the interval $[a, b]$, differentiable on (a, b) , and let $f(a) = f(b)$. Then there is a number c strictly between a and b such that $f'(c) = 0$.

Example: Let $f(x) = x^3 - 2x^2 + 1$, and observe $f(2) = f(0) = 1$. Since $f(x)$ is a polynomial, it is continuous and differentiable everywhere.

By Rolle's Theorem, we are guaranteed that $f'(x) = 0$ for *some* x in the interval $(0, 2)$. Which x fulfils this guarantee?

Rolle's Theorem – Theorem 2.13.1

Let $f(x)$ be **continuous** on the interval $[a, b]$, **differentiable** on (a, b) , and let $f(a) = f(b)$. Then there is a number c strictly between a and b such that $f'(c) = 0$.

Suppose $a < b$ and $f(a) = f(b)$, $f(x)$ is **continuous** over $[a, b]$, and $f(x)$ is **differentiable** over (a, b) .

How many different values of x between a and b have $f'(x) = 0$?

- A. 0 or 1
- B. 1
- C. 0, 1, or more
- D. 1 or more
- E. I'm not sure

2.13: Mean Value Theorem

Rolle's Theorem – Theorem 2.13.1

Let $f(x)$ be continuous on the interval $[a, b]$, differentiable on (a, b) , and let $f(a) = f(b)$. Then there is a number c strictly between a and b such that $f'(c) = 0$.

How many different values of x between a and b have $f'(x) = 0$?

A. 0 or 1

B. 1

C. 0, 1, or more

D. 1 or more

E. I'm not sure

Suppose $a < b$ and $f(a) = f(b)$,
 $f(x)$ is continuous over $[a, b]$, and
 $f(x)$ is differentiable over (a, b) .

If there's not much agreement, flash the two examples, then let students vote again. If most students choose the wrong answer, show them the example, vote again. They'll likely ask whether this is the *only* example. We've seen infinite wiggling before.

Rolle's Theorem – Theorem 2.13.1

Let $f(x)$ be continuous on the interval $[a, b]$, differentiable on (a, b) , and let $f(a) = f(b)$. Then there is a number c strictly between a and b such that $f'(c) = 0$.

Suppose $f(x)$ is continuous and differentiable for all real numbers, and $f(x)$ has precisely seven roots, all different. How many roots does $f'(x)$ have?

- A. precisely six
- B. precisely seven
- C. at most seven
- D. at least six

Rolle's Theorem – Theorem 2.13.1

Let $f(x)$ be continuous on the interval $[a, b]$, differentiable on (a, b) , and let $f(a) = f(b)$. Then there is a number c strictly between a and b such that $f'(c) = 0$.

Suppose $f(x)$ is continuous and differentiable for all real numbers, and $f'(x)$ is also continuous and differentiable for all real numbers, and $f(x)$ has precisely seven roots, all different. How many roots does $f''(x)$ have?

- A. precisely six
- B. precisely five
- C. at most five
- D. at least five

Rolle's Theorem – Theorem 2.13.1

Let $f(x)$ be continuous on the interval $[a, b]$, differentiable on (a, b) , and let $f(a) = f(b)$. Then there is a number c strictly between a and b such that $f'(c) = 0$.

Suppose $f(x)$ is continuous and differentiable for all real numbers, and there are precisely three places where $f'(x) = 0$.

How many distinct roots does $f(x)$ have?

- A. at most three
- B. at most four
- C. at least three
- D. at least four

Rolle's Theorem – Theorem 2.13.1

Let $f(x)$ be continuous on the interval $[a, b]$, differentiable on (a, b) , and let $f(a) = f(b)$. Then there is a number c strictly between a and b such that $f'(c) = 0$.

Suppose $f(x)$ is continuous and differentiable for all real numbers, and $f'(x) = 0$ for precisely three values of x . How many distinct values x exist with $f(x) = 17$?

- A. at most three
- B. at most four
- C. at least three
- D. at least four

APPLICATIONS OF ROLLE'S THEOREM

Prove that the function $f(x) = x^3 + x - 1$ has at most one real root.

How would you show that $f(x)$ has precisely one real root?

Use Rolle's Theorem to show that the function
 $f(x) = \frac{1}{3}x^3 + 3x^2 + 9x - 3$ has at most two distinct real roots.

AVERAGE RATE OF CHANGE

What is the **average rate of change** of $f(x)$ from $x = 1$ to $x = 3$?

- A. 0
- B. 1
- C. 2
- D. 4
- E. I'm not sure

└ 2.13: Mean Value Theorem

└ Average Rate of Change

AVERAGE RATE OF CHANGE

What is the *average rate of change* of $f(x)$ from $x = 1$ to $x = 3$?

- A. 0
- B. 1
- C. 2
- D. 4
- E. I'm not sure

Rolle's Theorem tells us there is a spot where the derivative is 0; in this case, that's the same as the average rate of change.

AVERAGE RATE OF CHANGE

What is the **average rate of change** of $f(x)$ from $x = 2$ to $x = 7$?

- A. 0
- B. 3
- C. 5
- D. 15
- E. I'm not sure

└ 2.13: Mean Value Theorem

└ Average Rate of Change

AVERAGE RATE OF CHANGE

What is the *average rate of change* of $f(x)$ from $x = 2$ to $x = 7$?

- A. 0
- B. 3
- C. 5
- D. 15
- E. I'm not sure

Want a visual example that's simpler than the last one in order to illustrate Average RoC theorem. This also gives students a second chance to get the average RoC correct.

Rolle's Theorem and Average Rate of Change

Suppose $f(x)$ is **continuous** on the interval $[a, b]$, **differentiable** on the interval (a, b) , and $f(a) = f(b)$. Then there exists a number c strictly between a and b such that

$$f'(c) = 0 = \frac{f(b) - f(a)}{b - a}.$$

So there exists a point where the derivative is the same as the average rate of change.

Mean Value Theorem – Theorem 2.13.4

Let $f(x)$ be **continuous** on the interval $[a, b]$ and **differentiable** on (a, b) . Then there is a number c strictly between a and b such that:

$$f'(c) = \frac{f(b) - f(a)}{b - a}$$

That is: there is some point c in (a, b) where the instantaneous rate of change of the function is equal to the average rate of change of the function on the interval $[a, b]$.

Suppose you are driving along a long, straight highway with no shortcuts. The speed limit is 100 kph. A police officer notices your car going 90 kph, and uploads your plate and the time they saw you to their database. 150 km down this same straight road, 75 minutes later, another police officer notices your car going 85kph, and uploads your plates to the database. Then they pull you over, and give you a speeding ticket. Why were they justified?

According to [this website](#), Canada geese may fly 1500 miles in a single day under favorable conditions. It also says their top speed is around 70mph. Does this seem like a typo? (If it contradicts the Mean Value Theorem, it's probably a typo.)

The record for fastest wheel-driven land speed is around 700 kph. ¹
However, non-wheel driven cars (such as those powered by jet engines) have achieved higher speeds. ²
Suppose a driver of a jet-powered car starts a 10km race at 12:00, and finishes at 12:01. Did they beat 700kph?

¹(at time of writing) George Poteet,

https://en.wikipedia.org/wiki/Wheel-driven_land_speed_record

²https://en.wikipedia.org/wiki/Land_speed_record

Suppose you want to download a file that is 3000 MB (slightly under 3GB). Your internet provider guarantees you that your download speeds will always be between 1 MBPS (MB per second) and 5 MBPS (because you bought the cheap plan). Using the Mean Value Theorem, give an upper and lower bound for how long the download can take (assuming your providers aren't lying, and your device is performing adequately).

Suppose $1 \leq f'(t) \leq 5$ for all values of t , and $f(0) = 0$. What are the possible solutions to $f(t) = 3000$?

Notice: since the derivative exists for all real numbers, $f(x)$ is differentiable and continuous for all real numbers!

Corollary to the MVT

Let $a < b$ be numbers in the domain of $f(x)$ and $g(x)$, which are continuous over $[a, b]$ and differentiable over (a, b) .

If $f'(x) = 0$ for all x in (a, b) , then

If $f(c) \neq f(d)$, then $\frac{f(d)-f(c)}{d-c} \neq 0$, so $f'(e) \neq 0$ for some e .

2.13: Mean Value Theorem

Corollary to the MVT

Let $a < b$ be numbers in the domain of $f(x)$ and $g(x)$, which are continuous over $[a, b]$ and differentiable over (a, b) .

If $f'(x) = 0$ for all x in (a, b) , then

If $f(x) \neq f(b)$, then $\frac{f(b)-f(a)}{b-a} \neq 0$, so $f'(x) \neq 0$ for some c .

Explain what a “corollary” is.

Corollary to the MVT

Let $a < b$ be numbers in the domain of $f(x)$ and $g(x)$, which are continuous over $[a, b]$ and differentiable over (a, b) .

If $f'(x) = g'(x)$ for all x in (a, b) , then

Define a new function $k(x) = f(x) - g(x)$. Then $k'(x) = 0$ everywhere, so (by the last corollary) $k(x) = A$ for some constant A .

Corollary to the MVT

Let $a < b$ be numbers in the domain of $f(x)$ and $g(x)$, which are continuous over $[a, b]$ and differentiable over (a, b) .

If $f'(x) > 0$ for all x in (a, b) , then

If $f(c) > f(d)$ and $c < d$, then $\frac{f(d)-f(c)}{d-c} = \frac{\text{(negative)}}{\text{(positive)}} < 0$. Then $f'(e) < 0$ for some e between c and d .

Corollary to the MVT

Let $a < b$ be numbers in the domain of $f(x)$ and $g(x)$, which are continuous over $[a, b]$ and differentiable over (a, b) .

If $f'(x) < 0$ for all x in (a, b) , then

If $f(c) < f(d)$ and $c < d$, then $\frac{f(d)-f(c)}{d-c} = \frac{\text{(positive)}}{\text{(positive)}} > 0$. Then $f'(e) > 0$ for some e between c and d .

Mean Value Theorem – Theorem 2.13.4

Let $f(x)$ be **continuous** on the interval $[a, b]$ and **differentiable** on (a, b) . Then there is a number c strictly between a and b such that

$$f'(c) = \frac{f(b) - f(a)}{b - a}$$

WARNING: The MVT has two hypotheses.

- ▶ $f(x)$ has to be continuous on $[a, b]$.
- ▶ $f(x)$ has to be differentiable on (a, b) .

If either of these hypotheses are violated, the conclusion of the MVT can fail. Here are two examples.

Mean Value Theorem – Theorem 2.13.4

Let $f(x)$ be **continuous** on the interval $[a, b]$ and **differentiable** on (a, b) . Then there is a number c strictly between a and b such that

$$f'(c) = \frac{f(b) - f(a)}{b - a}$$

Example: Let $a = -1$, $b = 1$ and $f(x) = |x|$.

Mean Value Theorem – Theorem 2.13.4

Let $f(x)$ be **continuous** on the interval $[a, b]$ and **differentiable** on (a, b) . Then there is a number c strictly between a and b such that

$$f'(c) = \frac{f(b) - f(a)}{b - a}$$

Example: Let $a = 0$, $b = 1$ and $f(x) = \begin{cases} 0 & \text{if } x \leq 0 \\ 1 & \text{if } x > 0 \end{cases}$.
