

# TABLE OF CONTENTS

## Table of Contents

We'll start by introducing “big ideas” before we get to the actual textbook content. We use scenarios that have a lot of intuition behind them, rather than purely abstract examples.

We go through: constant rate of change, non-constant rate of change, average vs continuous rate of change, tangent and secant lines

# RATES OF CHANGE

Suppose the population of a small country was 1 million individuals in 1990, and is growing at a steady rate of 20,000 individuals per year.

## Definition

The **slope** of a line that passes through the points  $(x_1, y_1)$  and  $(x_2, y_2)$  is “rise over run”

$$\frac{\Delta y}{\Delta x} = \frac{y_2 - y_1}{x_2 - x_1}.$$

This is also called the **rate of change** of the function.

If a line has equation  $y = mx + b$ , its slope is  $m$ .

## Big Ideas

We see that the rate of change is the same whether measuring over one year (given information) or two years (calculated)

Suppose the population of a small country is given in the chart below.

## Definition

Let  $y = f(x)$  be a curve that passes through  $(x_1, y_1)$  and  $(x_2, y_2)$ . Then the **average rate of change** of  $f(x)$  when  $x_1 \leq x \leq x_2$  is

$$\frac{\Delta y}{\Delta x} = \frac{y_2 - y_1}{x_2 - x_1}$$

## Average Rate of Change and Slope

The **average rate of change** of a function  $f(x)$  on the interval  $[a, b]$  (where  $a \neq b$ ) is “change in output” divided by “change in input:”

$$\frac{f(b) - f(a)}{b - a}$$

If the function  $f(x)$  is a **line**, then the slope of the line is “rise over run,”

$$\frac{f(b) - f(a)}{b - a}$$

If a function is a line, its slope is the same as its average rate of change, which is the same for every interval.

If a function is not a line, its average rate of change might be different for different intervals, and we don't have a definition (yet) for its "slope."

If a function is a line, its slope is the same as its average rate of change, which is the same for every interval.

If a function is not a line, its average rate of change might be different for different intervals, and we don't have a definition (yet) for its "slope."

Say this frame out loud while **showing** the previous frame. It sums up our "big ideas" section.

At the end can add: let's think about what slope might mean in the context of rates of change for functions that aren't lines

How fast was this population growing in the year 2010? (What was its **instantaneous** rate of change?)

# Big Ideas

How fast was this population growing in the year 2010? (What was its *instantaneous* rate of change?)

Mention it was slower before 2010, and faster after 2010 “We can start by looking at an interval around 2010. ” show  $\pm 10$  as an example that will make students uncomfortable. Note that the average rate of change is the slope of the line between the two points, but the line and the curve look pretty different. Then move to  $\pm 1$ . “This is getting hard to see, so let’s zoom in.” Same, now note the line and the curve are getting closer.

“But we don’t care about 2009, or 2019. So let’s just look at Jan 2010 to Dec 2010.” More zooming. Note it’s basically a line now.

## Big Ideas

How fast was this population growing in the year 2010? (What was the *instantaneous* rate of change?)

So these are the big ideas we'll be thinking about: rates of change, measured as average over a large interval or over a very small one.

In the case of a line, average rate of change is the slope. In the case of a curve, sometimes we can zoom in close and the curve looks like a line. So the average rate of change over a small interval will look something like the slope of a line.

# TABLE OF CONTENTS

## Definition

The **secant line** to the curve  $y = f(x)$  through points  $R$  and  $Q$  is a line that passes through  $R$  and  $Q$ .

We call the slope of the secant line the **average rate of change of  $f(x)$  from  $R$  to  $Q$** .

## Definition

The **tangent line** to the curve  $y = f(x)$  at point  $P$  is a line that

- passes through  $P$  and
- has the same slope as  $f(x)$  at  $P$ .

We call the slope of the tangent line the **instantaneous rate of change of  $f(x)$  at  $P$** .

# 1.1 Drawing Tangents

## Definition

The **secant line** to the curve  $y = f(x)$  through points  $R$  and  $Q$  is a line that passes through  $R$  and  $Q$ .

We call the slope of the secant line the **average rate of change of  $f(x)$  from  $R$  to  $Q$** .

## Definition

The **tangent line** to the curve  $y = f(x)$  at point  $P$  is a line that

- passes through  $P$  and
- has the same slope as  $f(x)$  at  $P$ .

We call the slope of the tangent line the **instantaneous rate of change of  $f(x)$  at  $P$** .

Verbally: we haven't formally defined the slope of a curve yet, but think of it as the slope of the *line* that the curve looks like, if you zoom way in.

When P pops up, draw the tangent by hand before clicking to it, to demonstrate what you mean.

On the graph below, draw the secant line to the curve through points  $P$  and  $Q$ .

On the graph below, draw the tangent line to the curve at point  $P$ .
